# Session 4

Multi-test, multi-population models

Matt Denwood 2021-06-29

## Why stop at two tests?

In *traditional* diagnostic test evaluation, one test is assumed to be a gold standard from which all other tests are evaluated

So it makes no difference if you assess one test at a time or do multiple tests at the same time

Using a latent class model each new test adds new information - so we should analyse all available test results in the same model

## Simulating data

Simulating data using an arbitrary number of independent tests is quite straightforward:

```
# Parameter values to simulate:
N < -200
sensitivity \leftarrow c(0.8, 0.9, 0.95)
specificity \leftarrow c(0.95, 0.99, 0.95)
Populations <- 2
prevalence \leftarrow c(0.25,0.5)
data <- tibble(Population = sample(seq len(Populations), N,

    replace=TRUE)) %>%

 mutate(Status = rbinom(N, 1, prevalence[Population])) %>%
 mutate(Test1 = rbinom(N, 1, sensitivity[1]*Status +
 mutate(Test2 = rbinom(N, 1, sensitivity[2]*Status +
 mutate(Test3 = rbinom(N, 1, sensitivity[3]*Status +
 select(-Status)
```

Like for two tests, except it is now a 2x2x2 table

Like for two tests, except it is now a 2x2x2 table

```
Tally[1:8,p] ~ dmulti(prob[1:8,p], TotalTests[p])
# Probability of observing Test1- Test2- Test3-
prob[1,p] \leftarrow prev[p] * ((1-se[1])*(1-se[2])*(1-se[3]) +
              (1-prev[p]) * (sp[1]*sp[2]*sp[3])
# Probability of observing Test1+ Test2- Test3-
prob[2,p] \leftarrow prev[p] * (se[1]*(1-se[2])*(1-se[3])) +
              (1-prev[p]) * ((1-sp[1])*sp[2]*sp[3])
## snip ##
# Probability of observing Test1+ Test2+ Test3+
prob[3,p] <- prev[p] * (se[1]*se[2]*se[3]) +
              (1-prev[p]) * ((1-sp[1])*(1-sp[2])*(1-sp[3]))
```

Like for two tests, except it is now a 2x2x2 table

```
Tally[1:8,p] ~ dmulti(prob[1:8,p], TotalTests[p])
# Probability of observing Test1- Test2- Test3-
prob[1,p] \leftarrow prev[p] * ((1-se[1])*(1-se[2])*(1-se[3]) +
              (1-prev[p]) * (sp[1]*sp[2]*sp[3])
# Probability of observing Test1+ Test2- Test3-
prob[2,p] \leftarrow prev[p] * (se[1]*(1-se[2])*(1-se[3])) +
              (1-prev[p]) * ((1-sp[1])*sp[2]*sp[3])
## snip ##
# Probability of observing Test1+ Test2+ Test3+
prob[3,p] <- prev[p] * (se[1]*se[2]*se[3]) +
              (1-prev[p]) * ((1-sp[1])*(1-sp[2])*(1-sp[3]))
```

• We need to take extreme care with these equations, and the multinomial tabulation!!!

## Are the tests conditionally independent?

- Example: we have one blood, one milk, and one faecal test
  - But the blood and milk test are basically the same test
  - Therefore they are more likely to give the same result

## Are the tests conditionally independent?

- Example: we have one blood, one milk, and one faecal test
  - But the blood and milk test are basically the same test
  - Therefore they are more likely to give the same result
- Example: we test people for COVID using an antigen test on a nasal swab, a PCR test on a throat swab, and the same antigen test on the same throat swab
  - The virus may be present in the throat, nose, neither, or both
  - But we use the same antigen test twice
    - Might it cross-react with the same non-target virus?

## Are the tests conditionally independent?

- Example: we have one blood, one milk, and one faecal test
  - But the blood and milk test are basically the same test
  - Therefore they are more likely to give the same result
- Example: we test people for COVID using an antigen test on a nasal swab, a PCR test on a throat swab, and the same antigen test on the same throat swab
  - The virus may be present in the throat, nose, neither, or both
  - But we use the same antigen test twice
    - Might it cross-react with the same non-target virus?
- In both situations we have pairwise correlation between some of the tests

## Dealing with correlation

It helps to consider the data simulation as a (simplified) biological process (where my parameters are not representative of real life!):

```
# The probability of infection with COVID in two populations:
prevalence <- c(0.01, 0.05)
# The probability of shedding COVID in the nose conditional on
nose_shedding <- 0.8
# The probability of shedding COVID in the throat conditional on
throat_shedding <- 0.8
# The probability of detecting virus with the antigen test:
antigen detection <- 0.75
# The probability of detecting virus with the PCR test:
pcr detection <- 0.999
# The probability of random cross-reaction with the antiqen test:
antigen crossreact <- 0.05
# The probability of random cross-reaction with the PCR test:
pcr crossreact <- 0.01
```

## Dealing with correlation

It helps to consider the data simulation as a (simplified) biological process (where my parameters are not representative of real life!):

```
# The probability of infection with COVID in two populations:
prevalence <- c(0.01, 0.05)
# The probability of shedding COVID in the nose conditional on
nose_shedding <- 0.8
# The probability of shedding COVID in the throat conditional on
throat_shedding <- 0.8
# The probability of detecting virus with the antigen test:
antigen detection <- 0.75
# The probability of detecting virus with the PCR test:
pcr detection <- 0.999
# The probability of random cross-reaction with the antiqen test:
antigen crossreact <- 0.05
# The probability of random cross-reaction with the PCR test:
pcr crossreact <- 0.01
```

Note: cross-reactions are assumed to be independent!

#### Simulating latent states:

#### Simulating test results:

```
covid data <- covid data %>%
  ## The nose swab antigen test may be false or true positive:
 mutate(NoseAG = case when(
   Nose == 1 ~ rbinom(N, 1, antigen_detection),
   Nose == 0 ~ rbinom(N, 1, antigen_crossreact)
 )) %>%
 ## The throat swab antigen test may be false or true positive:
 mutate(ThroatAG = case when(
   Throat == 1 ~ rbinom(N, 1, antigen_detection),
   Throat == 0 ~ rbinom(N, 1, antigen crossreact)
 )) %>%
  ## The PCR test may be false or true positive:
 mutate(ThroatPCR = case_when(
   Throat == 1 ~ rbinom(N, 1, pcr_detection),
   Throat == 0 ~ rbinom(N, 1, pcr crossreact)
 ))
```

The overall sensitivity of the tests can be calculated as follows:

### The overall specificity of the tests is more straightforward:

```
covid_specificity <- c(
    # Nose antigen:
    1 - antigen_crossreact,
    # Throat antigen:
    1 - antigen_crossreact,
    # Throat PCR:
    1 - pcr_crossreact
)
covid_specificity
## [1] 0.95 0.95 0.99</pre>
```

The overall specificity of the tests is more straightforward:

```
covid_specificity <- c(
    # Nose antigen:
    1 - antigen_crossreact,
    # Throat antigen:
    1 - antigen_crossreact,
    # Throat PCR:
    1 - pcr_crossreact
)
covid_specificity
## [1] 0.95 0.95 0.99</pre>
```

However: this assumes that cross-reactions are independent!

```
prob[1,p] <- prev[p] * ((1-se[1])*(1-se[2])*(1-se[3])
                         +covse12 +covse13 +covse23) +
              (1-prev[p]) * (sp[1]*sp[2]*sp[3]
                              +covsp12 +covsp13 +covsp23)
prob[2,p] \leftarrow prev[p] * (se[1]*(1-se[2])*(1-se[3])
                            -covse12 -covse13 +covse23) +
               (1-prev[p]) * ((1-sp[1])*sp[2]*sp[3]
                               -covsp12 -covsp13 +covsp23)
## snip ##
# Covariance in sensitivity between tests 1 and 2:
covse12 ~ dunif( (se[1]-1)*(1-se[2]).
                     \min(se[1], se[2]) - se[1]*se[2])
# Covariance in specificity between tests 1 and 2:
covsp12 \sim dunif((sp[1]-1)*(1-sp[2]),
                     min(sp[1], sp[2]) - sp[1]*sp[2])
```

```
prob[1,p] <- prev[p] * ((1-se[1])*(1-se[2])*(1-se[3])
                         +covse12 +covse13 +covse23) +
              (1-prev[p]) * (sp[1]*sp[2]*sp[3]
                              +covsp12 +covsp13 +covsp23)
prob[2,p] \leftarrow prev[p] * (se[1]*(1-se[2])*(1-se[3])
                            -covse12 -covse13 +covse23) +
               (1-prev[p]) * ((1-sp[1])*sp[2]*sp[3]
                               -covsp12 -covsp13 +covsp23)
## snip ##
# Covariance in sensitivity between tests 1 and 2:
covse12 ~ dunif( (se[1]-1)*(1-se[2]).
                     \min(se[1], se[2]) - se[1]*se[2])
# Covariance in specificity between tests 1 and 2:
covsp12 \sim dunif((sp[1]-1)*(1-sp[2]),
                     min(sp[1], sp[2]) - sp[1]*sp[2])
```

It is quite easy to get the terms slightly wrong!

## Template Hui-Walter

The model code and data format for an arbitrary number of populations (and tests) can be determined automatically using the template\_huiwalter function from the runjas package:

```
template_huiwalter(
  covid_data %>% select(Population, NoseAG, ThroatAG, ThroatPCR),
  outfile = 'covidmodel.txt')
```

This generates self-contained model/data/initial values etc

```
model{
    ## Observation layer:
    # Complete observations (N=20000):
    for(p in 1:Populations){
        Tally_RRR[1:8,p] ~ dmulti(prob_RRR[1:8,p], N_RRR[p])
        prob_RRR[1:8,p] <- se_prob[1:8,p] + sp_prob[1:8,p]</pre>
    }
    ## Observation probabilities:
    for(p in 1:Populations){
        # Probability of observing NoseAG- ThroatAG- ThroatPCR- from a
        \hookrightarrow true positive::
        se_{prob}[1,p] \leftarrow prev[p] * ((1-se[1])*(1-se[2])*(1-se[3])
        \hookrightarrow +covse12 +covse13 +covse23)
        # Probability of observing NoseAG- ThroatAG- ThroatPCR- from a
        sp_prob[1,p] \leftarrow (1-prev[p]) * (sp[1]*sp[2]*sp[3] +covsp12
        \hookrightarrow +covsp13 +covsp23)
        # Probability of observing NoseAG+ ThroatAG- ThroatPCR- from a
```

```
## Inits:
inits{
"se" <- c(0.5, 0.99, 0.5)
"sp" <- c(0.99, 0.75, 0.99)
"prev" <- c(0.05, 0.95)
# "covse12" <- 0
# "covse13" <- 0
# "covse23" <- 0
# "covsp12" <- 0
# "covsp13" <- 0
# "covsp23" <- 0
inits{
"se" <- c(0.99, 0.5, 0.99)
"sp" <- c(0.75, 0.99, 0.75)
"prev" <- c(0.95, 0.05)
# "covse12" <- 0
# "covse13" <- 0
# "covse23" <- 0
# "covsp12" <- 0
# "covsp13" <- 0
# "covsp23" <- 0
```

# And can be run directly from R:

results <- run.jags('covidmodel.txt')
results</pre>

	Lower95	Median	Upper95	SSeff	psrf
se[1]	0.581	0.632	0.681	8852	1.000

covsp23	0.000	0.000	0.000	NA	NA

## Template Hui-Walter

- Modifying priors must still be done directly in the model file
  - Same for adding .RNG.seed and the deviance monitor
- The model needs to be re-generated if the data changes
  - But remember that your modified priors will be reset
- There must be a single column for the population (as a factor), and all of the other columns (either factor, logical or numeric) are interpreted as being test results

## Template Hui-Walter

- Modifying priors must still be done directly in the model file
  - Same for adding .RNG.seed and the deviance monitor
- The model needs to be re-generated if the data changes
  - But remember that your modified priors will be reset
- There must be a single column for the population (as a factor), and all of the other columns (either factor, logical or numeric) are interpreted as being test results
- Covariance terms are all deactivated by default

## **Activating covariance terms**

Find the lines for the covariances that we want to activate (i.e. the two Throat tests):

```
# Covariance in sensitivity between ThroatAG and ThroatPCR tests: # covse23 ~ dunif( (se[2]-1)*(1-se[3]) , min(se[2],se[3]) - se[2]*se[3] \hookrightarrow ) ## if the sensitivity of these tests may be correlated covse23 <- 0 ## if the sensitivity of these tests can be assumed to be \hookrightarrow independent # Covariance in specificity between ThroatAG and ThroatPCR tests: # covsp23 ~ dunif( (sp[2]-1)*(1-sp[3]) , min(sp[2],sp[3]) - sp[2]*sp[3] \hookrightarrow ) ## if the specificity of these tests may be correlated covsp23 <- 0 ## if the specificity of these tests can be assumed to be \hookrightarrow independent
```

#### And edit so it looks like:

```
# Covariance in sensitivity between ThroatAG and ThroatPCR tests: covse23 ~ dunif( (se[1]-1)*(1-se[2]) , min(se[1],se[2]) - se[1]*se[2] ) 

\hookrightarrow ## if the sensitivity of these tests may be correlated 

# covse23 <- 0 ## if the sensitivity of these tests can be assumed to 

\hookrightarrow be independent 

# Covariance in specificity between ThroatAG and ThroatPCR tests: covsp23 ~ dunif( (sp[1]-1)*(1-sp[2]) , min(sp[1],sp[2]) - sp[1]*sp[2] ) 

\hookrightarrow ## if the specificity of these tests may be correlated 

# covsp23 <- 0 ## if the specificity of these tests can be assumed to 

\hookrightarrow be independent
```

### [i.e. swap the comments around]

You will also need to uncomment out the relevant initial values for BOTH chains (on lines 117-122 and 128-133):

```
# "covse12" <- 0
# "covse13" <- 0
# "covse23" <- 0
# "covsp12" <- 0
# "covsp13" <- 0
# "covsp23" <- 0
```

### So that they look like:

```
# "covse12" <- 0
# "covse13" <- 0
"covse23" <- 0
# "covsp12" <- 0
# "covsp13" <- 0
```

```
results <- run.jags('covidmodel.txt', sample=50000)
results
##
## JAGS model summary statistics from 100000 samples (chains = 2;
   adapt+burnin = 5000):
\hookrightarrow
##
##

#### **Practical considerations**

- Correlation terms add complexity to the model in terms of:
  - Opportunity to make a coding mistake
  - Reduced identifiability

#### **Practical considerations**

- Correlation terms add complexity to the model in terms of:
  - Opportunity to make a coding mistake
  - Reduced identifiability
- The template\_huiwalter function helps us with coding mistakes
- Only careful consideration of covariance terms can help us with identifiability

#### **Practical considerations**

- Correlation terms add complexity to the model in terms of:
  - Opportunity to make a coding mistake
  - Reduced identifiability
- The template\_huiwalter function helps us with coding mistakes
- Only careful consideration of covariance terms can help us with identifiability
- We will return to these themes tomorrow!

# Practical session 4

#### Points to consider

- 1. How does including a third test impact the inference for the first two tests?
- 2. What happens if we include correlation between tests?
- 3. Can we include correlation if we only have 2 tests?

## Summary

- Including multiple tests is technically easy
  - But philosophically more difficult!!!
- Complexity of adding correlation terms increases non-linearly with more tests
  - Probably best to stick to correlations with biological justification?
- Adding/removing test results may change the posterior for
  - Other test Se / Sp
  - Prevalence

### Homework

Think about what exactly the latent class is in these situations:

- 1. An antigen plus antibody test
- 2. Two antibody tests
